

The regional maps illustrating the regional river flows for five members of the Met Office ensemble of rainfall forecasts give some indication of the range of possible river flows in the coming months. As noted previously, the actual flows could be more extreme than the flows generated by either the lowest or highest members of the rainfall ensemble.

The bar charts (below) give further insight into the range of river flow forecasts by considering all members of the forecast rainfall ensemble. The regional bar charts show the percentage of ensemble forecasts falling in each of the flow categories as generated by the monthly-resolution water-balance model. As before results are averaged by region then ranked in terms of 49 years of historical regional flow estimates (1962 – 2010).

SUMMARY: This month, following below average rainfall for much of Britain it is likely that river flows will be *normal* or below in all regions. Some regions could have *Exceptionally Low* flows in November (e.g. Southern, Wales, Wessex). **Over the next 3 months** it is likely that river flows will be in the *Normal range* or below across Britain.
