

SUMMARY

The outlook for June and for June–August is that below normal river flows are likely in south Wales and southern and central England, and normal to below normal flows elsewhere. Groundwater levels in June and over the three-month timeframe are likely to be normal to below normal across most of the UK.

Rainfall:

Rainfall in May was below average across Wales and East Anglia, although elsewhere in England conditions were more variable owing to localised rainfall. Northern Ireland recorded above average rainfall and north-west Scotland was exceptionally wet.

The rainfall outlook (issued by the Met Office on 30.05.2022) for June and for the June–August period suggests that there is an increased likelihood of near-average rainfall rather than wet or dry weather.

River flows

River flows in May were generally below normal or lower across England and Wales, notably so in south-west England and south Wales. New monthly flow minima for May were established on some rivers in south Wales and the Midlands.

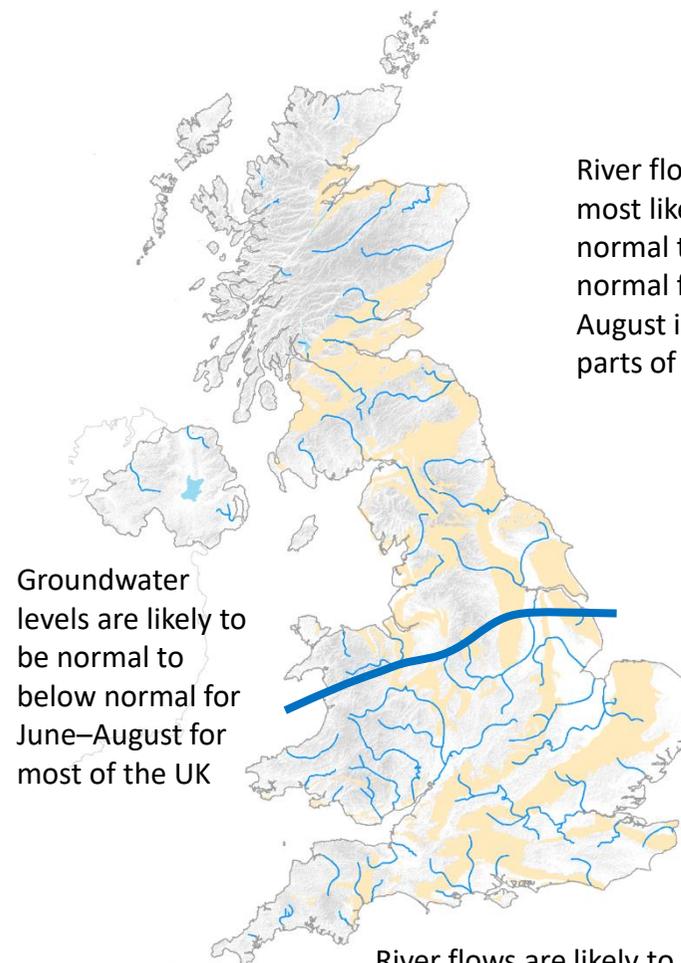

River flows in June are likely to be below normal across much of south Wales and southern and central England, with high confidence in outlooks for continued low flows for some catchments in south-east England. Elsewhere, normal to below normal flows are most likely. The same scenario is likely over the three-month timeframe, with below normal flows particularly likely in some catchments in south-east England.

Groundwater

Groundwater levels in May were normal to below normal across most of the UK. Levels in south Wales and in some boreholes in southern England and southern and eastern Scotland were notably low.

Levels in June are likely to be normal to below normal in most boreholes. Notably low groundwater levels are particularly likely for some boreholes in southern England and south Wales. The three-month outlook is similar to the one-month outlook, though with below normal levels tending more towards the normal range in some boreholes in southern England.

The Hydrological Outlook UK provides an outlook for the water situation for the UK over the next three months and beyond. For guidance on how to interpret the outlook, a wider range of information, and a full description of underpinning methods, please visit the website: www.hydoutuk.net

River flows are most likely to be normal to below normal for June–August in northern parts of the UK

Groundwater levels are likely to be normal to below normal for June–August for most of the UK

River flows are likely to be below normal for June and over June–August for southern and central England, and south Wales

Shaded areas show principal aquifers

About the Hydrological Outlook:

This document presents an outlook for the UK water situation for the next 1 – 3 months and beyond, using observational datasets, meteorological forecasts and a suite of hydrological modelling tools. The outlook is produced in a collaboration between the UK Centre for Ecology and Hydrology (UKCEH), British Geological Survey (BGS), the Met Office, the Environment Agency (EA), Natural Resources Wales (NRW), the Scottish Environment Protection Agency (SEPA), and for Northern Ireland, the Department for Infrastructure – Rivers (DfIR).

Data and Models:

The Hydrological Outlook depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged. Historic river flow and groundwater data are sourced from the UK National River Flow Archive and the National Groundwater Level Archive. Contemporary data are provided by the EA, SEPA, NRW and DfIR. These data are used to initialise hydrological models, and to provide outlook information based on statistical analysis of historical analogues.

Climate forecasts are produced by the Met Office. Hydrological modelling is undertaken by UKCEH using the Grid-to-Grid, PDM and CLASSIC hydrological models and by the EA using CATCHMOD. Hydrogeological modelling uses the R-groundwater model run by BGS and CATCHMOD run by the EA. Supporting documentation is available from the Outlooks website:

<https://www.hydoutuk.net/about/methods>

Presentation:

The language used in the summary presented overleaf generally places flows and groundwater levels into just three classes, i.e. below normal, normal, and above normal. However, the underpinning methods use as many as seven classes as defined in the graphic to the right, i.e. the summary uses a simpler classification than some of the methods. On those occasions when it is appropriate to provide greater discrimination at the extremes the terminology and definitions of the seven class scheme will be adopted.

Percentile range of historic values for relevant month	
Exceptionally high flow	> 95
Notably high flow	87-95
Above normal	72-87
Normal range	28-72
Below normal	13-28
Notably low flow	5-13
Exceptionally low flow	< 5
